GEOPHYSICAL WELL-LOG DATABASE FOR
THE GULF COAST AQUIFER SYSTEMS,
SOUTH-CENTRAL UNITED STATES

By Terry A. Wilson and R.L. Hosman

ABSTRACT

As part of the U.S. Geological Survey's Regional Aquifer-System Analysis (RASA) program, the Gulf Coast RASA was begun to investigate ground-water flow systems in the Coastal Plain of the south-central United States. Three regional aquifer systems are identified in the area. The Mississippi embayment aquifer system and the Texas coastal uplands aquifer system are composed predominantly of Eocene sediments; the coastal lowlands aquifer system is composed predominantly of Oligocene and younger sediments. Automated data-processing techniques were chosen to facilitate a study of this magnitude. A computer database of information derived from almost 1,000 geophysical well logs was constructed to support the delineation of the geohydrologic framework of the study area and the simulation of ground-water flow. The database contains entries pertaining primarily to physical characteristics of the hydrologic units.

INTRODUCTION

Background

The U.S. Geological Survey began a program in 1978 to investigate regional ground-water systems throughout the Nation. A major objective of the Regional Aquifer-System Analysis (RASA) program is to provide an understanding of ground-water flow systems on a regional scale (Bennett, 1979). Natural hydrologic boundaries, rather than political boundaries, have been used to determine areas to be studied. The Gulf Coast RASA study area consists of about 230,000 square miles onshore in Louisiana and parts of Alabama, Arkansas, Florida, Illinois, Kentucky, Mississippi, Missouri, Tennessee, and Texas. The study area contains an additional 60,000 square miles offshore on the Continental Shelf, as the aquifers extend beyond the coastline beneath the Gulf of Mexico. The extent of the Gulf Coast RASA study area is shown on plate 1.

Three regional aquifer systems are delineated in the Gulf Coast RASA study area (Grubb, 1984). The Mississippi embayment aquifer system and the Texas coastal uplands aquifer system are composed predominantly of Eocene sediments; the coastal lowlands aquifer system is composed predominantly of Oligocene and younger sediments. Each of these systems consists of thousands of feet of sediments, which contain numerous aquifers and confining units. Some of these geohydrologic units are regionally extensive, whereas others are of local importance. In order to quantitatively describe the groundwater hydrology, each of these systems was subdivided into discrete geo-hydrologic units. It became obvious early in this study that timely and accurate completion of work of this magnitude would require the techniques of automated data processing. Therefore, a computer database of information derived from geophysical well logs was constructed to support the delineation of the geohydrologic framework of the study area and the simulation of ground-water flow.

Purpose and Scope

The purpose of this report is to describe the contents of a database containing machine-readable information derived from geophysical well logs, present a summary of the data, and provide computer-generated tables of the data used for constructing maps of the geohydrologic units in the study area. These data also are being used in conjunction with computer-based interpolation techniques to construct data arrays for ground-water flow models.

Most of the data regarding physical characteristics of geologic and geohydrologic units studied in the Gulf Coast RASA were derived from geophysical well logs. Some of the data were also used in making water-quality calulations. The logs were almost entirely electrical or induction-electrical surveys of wells drilled by the petroleum industry. A few gamma ray and single-point electrical logs of water wells and nonpetroleum test wells were used where other data were not available. Oil-test logs generally were obtained from commercial sources, and logs of water wells and nonpetroleum tests were available from U.S. Geological Survey files.

CREATION OF GEOPHYSICAL WELL-LOG DATABASE

The logs used in the study were selected on the basis of two criteria: spatial distribution and interval logged. Because of the size of the study area, approximately 290,000 square miles, a density of one log per 400 square miles (20-mile spacing) was chosen as one that would produce representative regional data and still keep the data base at a manageable size. It was possible to maintain this distribution in nearly the entire area, owing to the fact that petroleum exploration is widespread throughout the Coastal Plain.

Where possible, the interval logged also was given consideration if more than one log was available for a given site. The top of the logged interval may be tens, hundreds, or even thousands of feet below land surface, and the bottom of the log varies with the depth of the hole. Log selection was determined by best overall coverage.

Data obtained from the geophysical logs to create the database included depths to the top and the thickness of geologic and hydrologic units. Other geohydrologic unit data include: (1) Thickness and depth of sands more than 20 ft thick in aquifer units and thickness and depth of major clays in confining units; (2) spontaneous-potential and formation-resistivity values for sands greater than 20 ft thick in the aquifers, and average resistivity values for sands greater than 20 ft thick interbedded in the confining layers; and (3) cumulative thickness of all sands thicker than 20 ft in aquifer units and of all interbedded sands in confining units. Estimates of dissolved-solids concentrations in water were derived from calculations involving density, resistivity, and temperature of the drilling mud; resistivity and temperature of the mud filtrate; and bottom hole temperature in a procedure described by Weiss (1987).

The data were obtained directly from almost 1,000 geophysical logs, coded, and entered into a computer file designed to facilitate retrieval for listings or processing for interpretations and calculations. Machine-generated data lists, maps and graphs based on these files were used to construct the geohydrologic framework.

GEOHYDROLOGIC UNITS

Prior to this study, regional aquifers had been recognized insofar as the geologic units comprising them were recognized. However, geologic nomenclature is not uniform throughout the study area, and local names do not lend themselves to a regional perspective. The following designations were chosen to identify major geohydrologic units of regional extent (R.L. Hosman and J.S. Weiss, U.S. Geological Survey, written commun., 1986). The units are listed in sequence by associated model layer numbers that are used in multilayer simulation of ground-water flow in the aquifer systems and are not in descending order of units, the normal U.S. Geological Survey standard for geohydrologic units:

Regional model layer number	Hydrologic unit
1	McNairy-Nacatocah aquifer
2	Lower Wilcox aquifer
3	Middle Wilcox aquifer
4	Lower Claiborne-upper Wilcox aquifer
5	Middle Claiborne aquifer
6	Upper Claiborne aquifer
7	Zone E (lower Miocene-upper Oligocene deposits)
8	Zone D (middle Miocene deposits)
9	Zone C (lower Pliocene-upper Miocene deposits)
10	Zone B (lower Pleistocene-upper Pliocene deposits)
11	Mississippi River Valley alluvial aquifer and Zone A (Holocene-upper Pleistocene deposits)
12	Midway confining unit
13	Lower Claiborne confining unit
14	Middle Claiborne confining unit
15	Vicksburg-Jackson confining unit
16	Zone E confining unit
17	Zone D confining unit

The relation of these hydrologic units to aquifer systems in the study area is shown in table 1 in descending order.

Table 1.--Relation among aquifer systems, regional model layers, and aquifers, permeable zones, and confining units

Aquifer system	Regional model layer number	Geohydrologic units
Coastal lowlands	11	Zone A (Holocene-upper Pleistocene deposits)
	10	Zone B (lower Pleistocene-upper Pliocene deposits)
	9	Zone C (lower Pliocene-upper Miocene deposits)
	17	Zone D confining unit
	8	Zone D (middle Miocene deposits)
	16	Zone E confining unit
	7	Zone E (lower Miocene-upper Oligocene deposits)
	15	Vicksburg-Jackson confining unit
Texas coastal uplands and Mississippi embayment	11 *	Mississippi River Valley alluvial aquifer
	6	Upper Claiborne aquifer
	14	Middle Claiborne confining unit
	5	Middle Claiborne aquifer
	13	Lower Claiborne confining unit
	4	Lower Claiborne-upper Wilcox aquifer
	3	Middle Wilcox aquifer
	2 *	Lower Wilcox aquifer
	12	Midway confining unit
	1 *	McNairy-Nacatoch aquifer

* Not in Texas coastal uplands aquifer system

The data in each of the log files are listed in tables 2, 3, and 4. A statistical summary of the data contained in table 4 is presented in table 5. Preceding each table is a glossary-type explanation of the data presented in that table.

Explanation of data in table 2:

State--State in which the logged well was drilled.

County--County or parish in which the logged well was drilled. Off-shore logs are listed following county (parish) lists.

Log number--An alphanumeric system that uses the two-letter State abbreviation followed by a two-letter county (parish) abbreviation followed by a two-digit sequential number. For example, the second well numbered in Baldwin County, Alabama, would be ALBL02. Offshore numbers are composed of the single letter initial of the State and a three-digit API (American Petroleum Institute) number followed by a two-digit sequential number.

Log sequence number--Wells for which logs were used in this study were numbered sequentially for convenience in this report. The numbers begin at the northernmost well in the project area and end at the southernmost.

Latitude--Latitude of the logged well, in degrees to four decimal places.

Longitude--Longitude of the logged well, in degrees to four decimal places.

Depth logged from--The depth to the top of the logged interval, in feet. On electrical and induction-electrical logs it generally begins at the bottom of the uppermost string of casing. (The file contains some data for the interval between land surface and the top of the log. These data generally were derived from drillers' or geophysical logs of nearby test holes or water wells, or from published reports.)

Depth logged to--The bottom of the logged interval, in feet. It generally represents the bottom of the hole at the time of logging. If the bottom of the logged interval is within an aquifer system included in this study, it also is the maximum depth for which data exists in the file. If the bottom of the logged interval is below the base of the lowest aquifer system being studied, no data will have been entered into the file for depths below the base of that system. The bases of the aquifer systems are the Vicksburg-Jackson confining unit, the Midway confining unit, and the top of the geopressured zone. The geopressured zone is a zone of abnormally excessive fluid pressures that occurs in some Gulf Coast sediments. It is considered the base of the flow system for purposes of this study.

Land-surface altitude--The altitude of the land surface at the logged well, in feet above sea level. For wells drilled off-shore in the Gulf of Mexico, this number is the altitude of the sea floor.

Table 2.--Log number and sequence number, well locations, interval logged, and land-surface altitude, by State and County

Explanation of data in table 3:

Log sequence number--Wells for which logs were used in this study were numbered sequentially for convenience in this report. The numbers begin at the northernmost well in the project area and end at the southernmost.

Log number--An alphanumeric system that uses the two-letter State abbreviation followed by a two-letter county (parish) abbreviation followed by a two-digit sequential number. For example, the first well numbered in Ballard County, Kentucky, would be KYBA01. Offshore numbers are composed of the single letter initial of the State and a three-digit API (American Petroleum Institute) number followed by a two-digit sequential number.

County--County (parish) in which the logged well was drilled. Offshore logs are listed following county (parish) lists.

Company name--The name of the organization or individual that drilled the well, such as Little Egypt Oil Co.

Well name--Based on the owner of the mineral rights to the land (generally the landowner) on which the well is drilled and, in most instances, sequential well number such as Delaney, No. 1.

Table 3.--Log number and well location, company, and name, by log sequence number
[SL = State Lease]

Log se- quence number	Log number	County	Company	Well name
1	KYMC01	MC CRACKEN	Glen Mitchell	W.B. Jackson, No. 1

Explanation of data in table 4:

Log number--An alphanumeric system that uses the two-letter State abbreviation followed by a two-letter county (parish) abbreviation followed by a two-digit sequential number. For example, the second well numbered in Baldwin County, Alabama, would be ALBL02. Offshore numbers are composed of the single letter initial of the State and a three-digit API (American Petroleum Institute) number followed by a two-digit sequential number.

Layer number--Sequential number of layer, beginning with lowermost aquifer and numbering aquifers upward (1-11), then lowermost confining unit and numbering confining units upward (12-17).

Altitude of top--Altitude of top of a given layer in feet, relative to sea level.

Thickness--Total thickness of given layer in feet.

Sand percentage--Percentage of the total thickness of sand in a given layer.

Average dissolved solids--Average dissolved-solids concentration in water in a given layer as calculated from data obtained from geophysical well logs.

Average temperature--Average temperature of water in a given layer as determined by temperature-gradient and bottom-hole temperature data.

Table 4--Layer number; altitude of top, thickness, and sand percentage of layer; and average dissolved-solids concentration and temperature of water in layer; by log number.

[Average dissolved-solids concentration in water in thousands of milligrams per liter; average water temperature in degrees Celsius]

Log number	Layer number	Altitude of top (feet)	Thick- ness (feet)	Sand per- centage	Diss- olved solids	Tem- per- ature

Explanation of data in table 5:

Layer number--Sequential number of layer, beginning with lowermost aquifer and numbering aquifers upward (1-11), then lowermost confining unit and numbering confining units upward (12-17).

Number of points with valid data--Total number of layer-thickness values entered in file for given layer.

Maximum thickness--Largest value in file for layer thickness for given layer, in feet.

Mean thickness--Mean of thickness values in file for given layer, in feet.

Standard deviation of thickness--The square root of the mean of the squares of the deviations from the arithmetic mean of the distribution for given layer, in feet.

Maximum altitude of top--Highest altitude in file for the top of given layer relative to sea level, in feet.

Minimum altitude of top--Lowest altitude in file for the top of given layer relative to sea level, in feet.

Mean sand percentage--Mean percentage of the total thickness of sand in a given layer.

Standard deviation of sand percentage--Standard deviation of the percentage of the total thickness of given layer that is composed of sand, in feet.

Table 5.--Statistical summary of thickness, altitude of top, and sand percentages, by layer

Layer number	Number	Thickness			Altitude of top (feet)			Sand percentage (feet)		
		Maximum	Mean	Standard deviation	Maximum	Minimum	Mean	Standard deviation

DESCRIPTION OF COMPUTER TAPE FILE

The geophysical well-log database consists of the data shown in tables 2, 3, and 4 that are contained in two physical files on a magnetic tape in ASCII format. The following parameters are contained in the well log file:

File 1 is described by the following structure:

<u>Field positions</u>	<u>Parameters</u>
1-3	Log sequence number
4-9	Log number
10-17	Latitude
20-27	Longitude
30-35	Land surface altitude
40-45	Depth logged from
50-55	Depth logged to
60-75	State name
80-99	County (parish) name
100-146	Company name
150-198	Well name

File 2 is described by the following structure:

<u>Field positions</u>	<u>Parameters</u>
1-6	Log number
7-8	Layer number
10-20	Altitude of top
20-29	Thickness
30-39	Sand percentage
40-49	Dissolved solids
50-59	Temperature, degrees Celsius

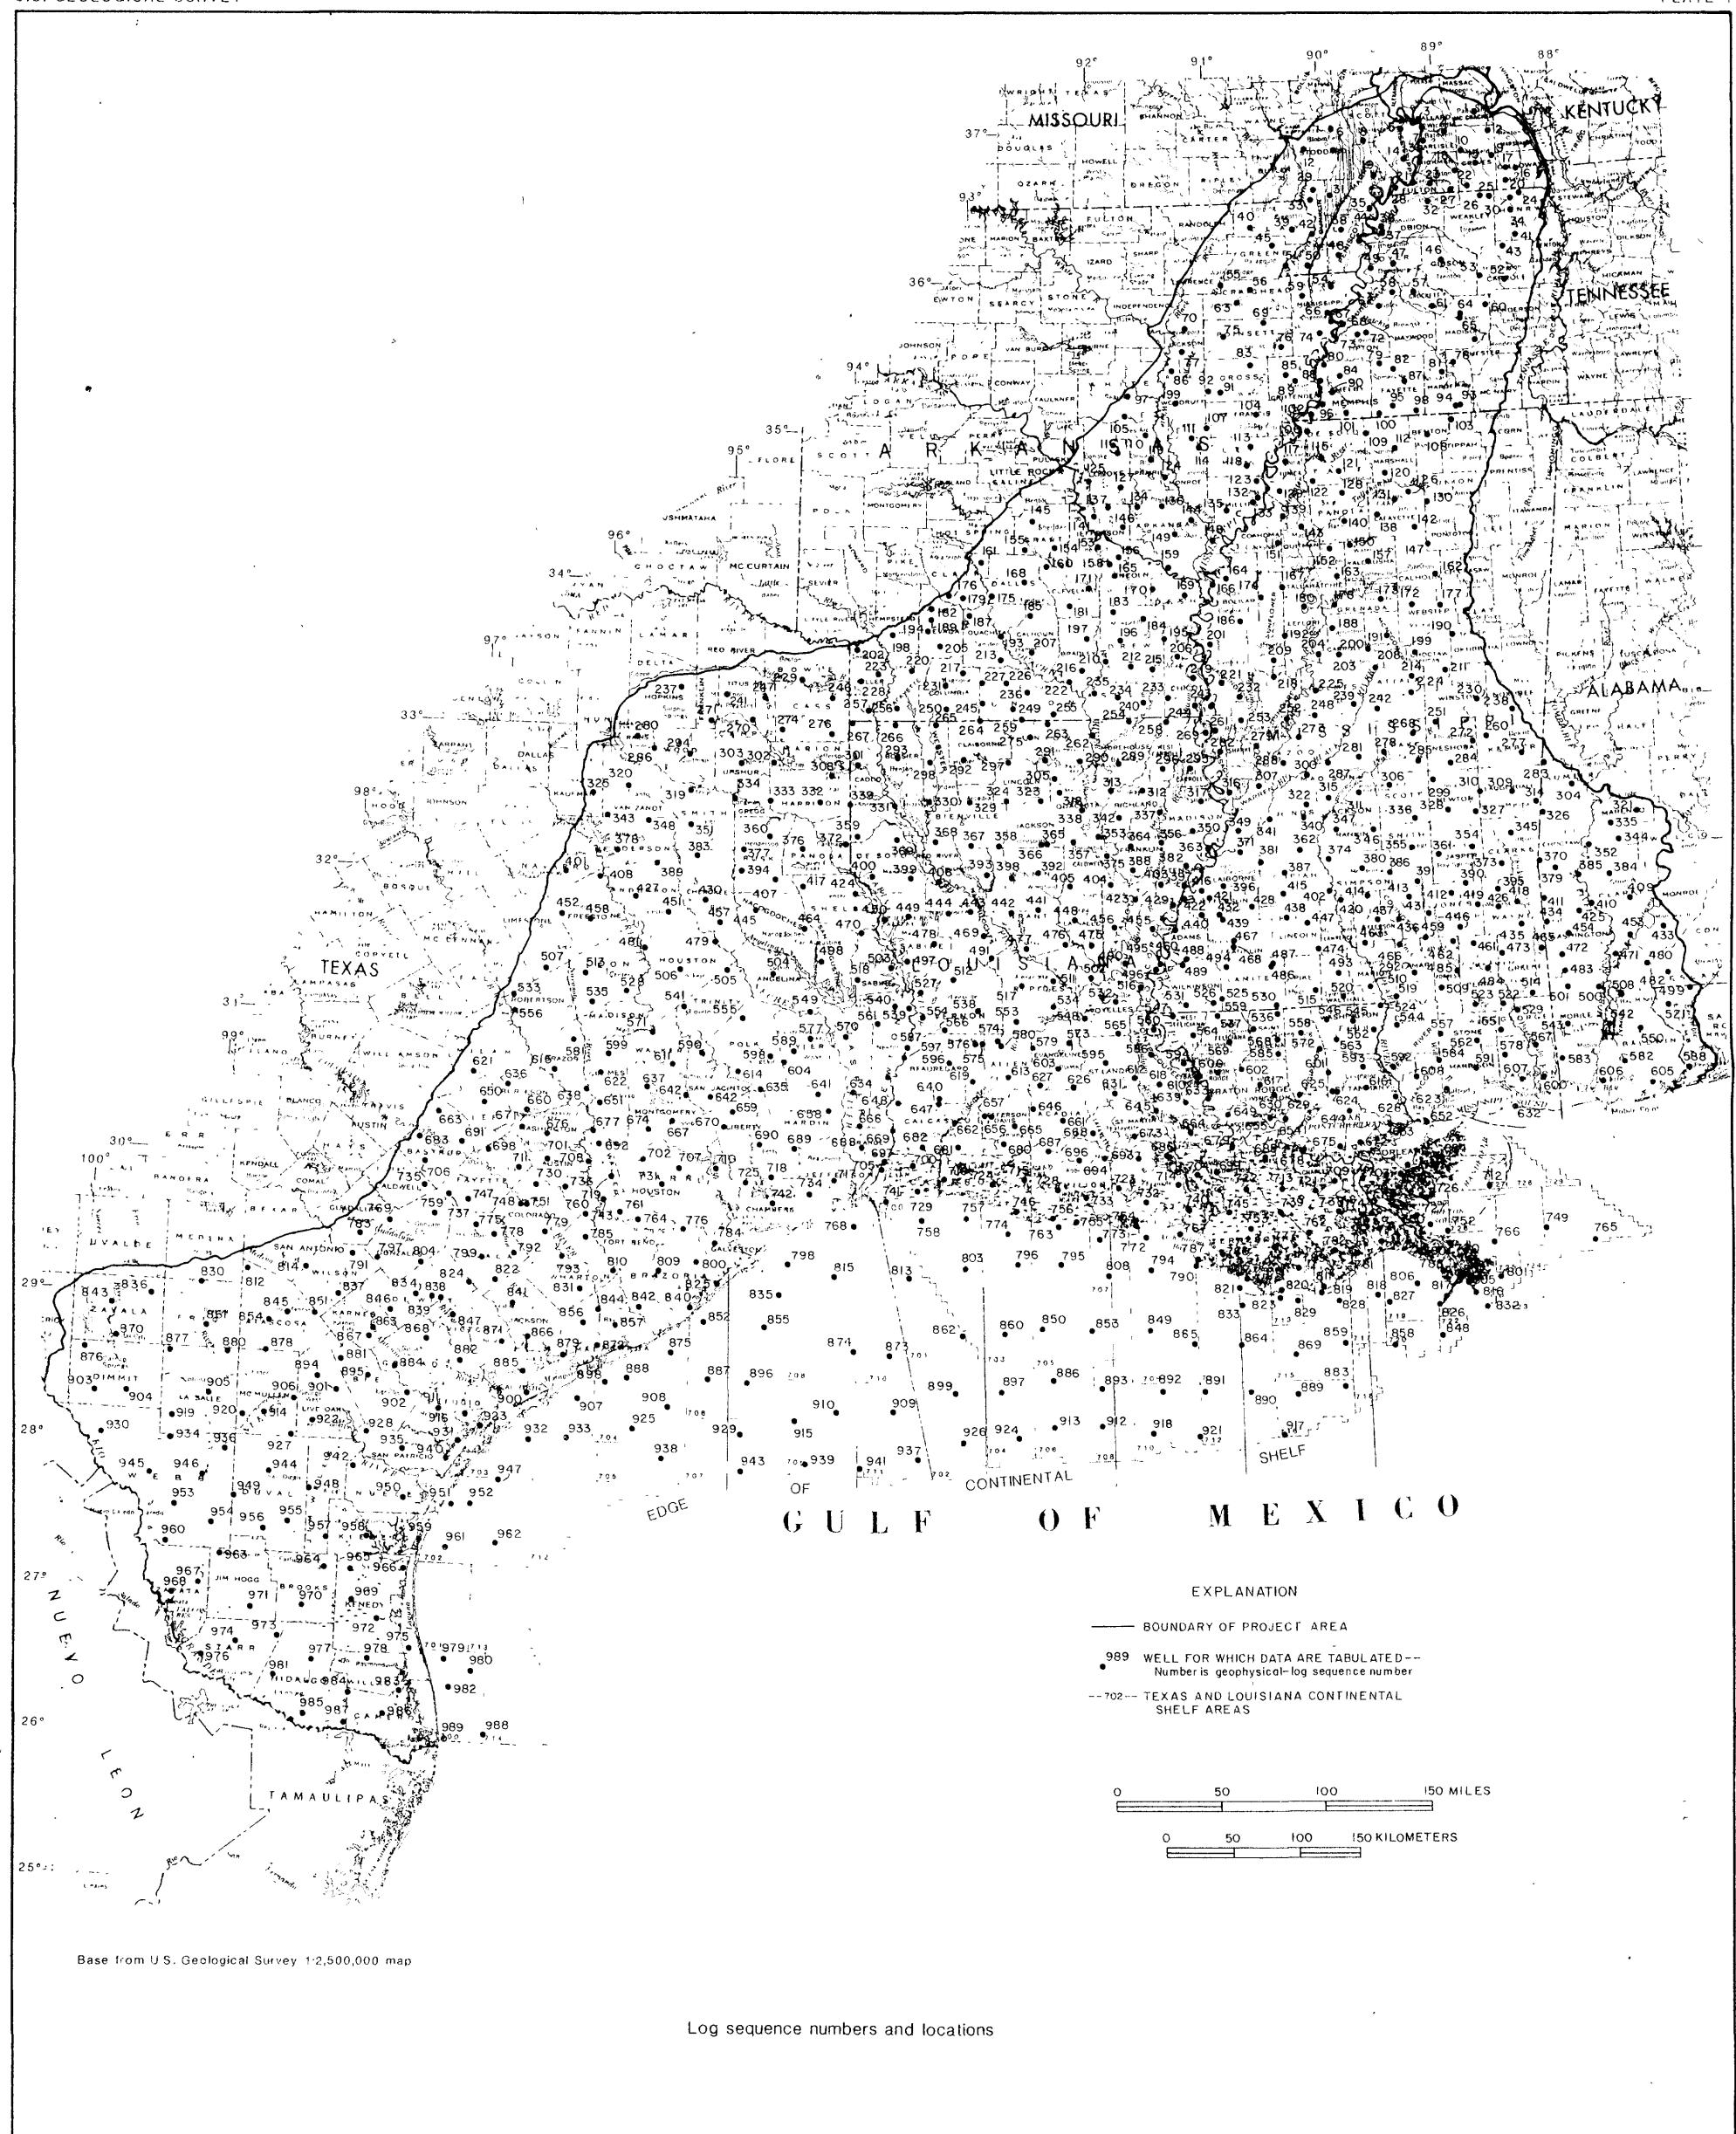

SUMMARY

Machine-readable files containing geohydrologic data derived from geophysical logs were assembled as part of the Gulf Coast RASA project and are stored on magnetic tape located in the Texas District Office of the U.S. Geological Survey, Water Resources Division.

A copy of the database may be obtained by contacting the computer services office of the U.S. Geological Survey, Water Resources Division in Austin, Texas. Inquiries should be addressed to: U.S. Geological Survey, WRD, Federal Building, Room 649, 300 East 8th Street, Austin, Texas 78701.
